

Improved meeting notes - ClubOS internship group

1) External variables / context effects

- **First-team performance** can act as an **external driver** that influences trends across other departments (e.g., **sales**, **eCommerce**, **social media**, overall engagement).
- Implication: when we observe KPI changes (spikes/drops), we should consider that part of the movement may be explained by **non-digital contextual factors** (match results, season timing, media attention).

2) KPI analysis should be "system-level" (KPIs influence each other)

- It's important to **analyse KPIs together rather than in isolation**, focusing on how one metric may influence another.
 - Goal: identify **relationships** (cause-effect where possible, or at least correlation) across the digital ecosystem (web/app/streaming/eCommerce), instead of reading each KPI as a standalone number.

3) Club investments/events can create measurable digital impacts (example mentioned)

- Club investments or major events (e.g., a high-profile player signing) can generate **large, measurable impacts** on digital metrics.
- Example discussed: a "Mbappé-type" signing leading to an **eCommerce record**.
- Implication: these events can explain **expected spikes** and should be accounted for when labelling something as an anomaly.

4) Interpreting conversion rate vs. user volume (clarifying the two cases)

The "positive/negative" labels are **not absolute**—they depend on context and objectives.

Case A — Low conversion rate with many users

- Could be **positive** if it reflects **top-of-funnel expansion** (more reach, broader audience, higher awareness).
- Could also be a warning signal if the increased traffic is **lower-intent** or if there are **funnel/UX issues**.
- Conclusion: treat as a **signal to interpret**, not automatically "good."

Case B — High conversion rate with few users

- Could be **negative** if performance is good only on a small base (e.g., very "warm" users), while **acquisition/scale is limited**.
- Could be normal in targeted scenarios, but by default it raises the question: are we **too narrow** in reach?
- Conclusion: also a **signal**, not automatically "bad."

Key point

- Conversion rate should be interpreted alongside **volume** and **historical behaviour** (see next section), not as a standalone KPI.

5) Use historical trends to avoid misleading interpretations

- To mitigate the two issues above, use **historical trends** as a baseline (what is "normal" for this club/asset).
- This helps distinguish:
 - a **structural change** (something truly improved or broke)
 - from an **expected fluctuation** driven by seasonality or external context.

6) Dependent vs. independent variables

- When analyzing patterns, separate:
 - **independent variables** (drivers/inputs, often external or upstream)
 - **dependent variables** (outcomes/results observed downstream)
- This improves clarity when discussing what might be causing what, and reduces the risk of mixing up cause and effect.

7) Next step: share the tool with the supervisor for hands-on feedback

- Action item: **give the supervisor access to the tool** so they can explore it directly.
- Goal: get **more detailed, concrete feedback** (usability, clarity of insights/priorities, what is missing to make it decision-ready).
